

1. Section one

Bob's change: explicit name and explicit color.

Alice's change: explicit name, automatic hash color.

Carol's change: nothing registered at all, automatic hash color and the raw id as display name.

A real reviewer's change, for comparison — must land on a color from the reviewer palette, never colliding with any author's.

First occurrence of a bare (number-less) author anchor — reused below, and never answered by any note/exchange at all.

Second occurrence of the same bare anchor. Neither this nor the one above should ever trigger “no matching exchange”, bare anchors being exempt by construction.

Numbered author anchor with no matching exchange — `require-exchange` is still at its default (`true`) here, so this should warn.

Numbered author anchor with no matching exchange, but `require-exchange: false` is now active — should NOT warn.

George's change — its note, in the response document, is written after a `comment-word/change-word` override that lives entirely inside `response.pdf` (see below): a set-revisions call in the manuscript would apply to **all** of `response.pdf` regardless of where within the manuscript it sits, since the whole of `response.pdf` comes after the whole of `manuscript.pdf` in bundle position — state resolves by absolute position in the bundle, not by “same document”. Verified directly; documented in `CLAUDE.md`.

A reviewer change, its exchange also written after the same override, in `response.pdf`.

Bare anchor used once via `note()` and once via `exchange()`'s two-argument form in the response document — the two must render identically.
